**ABSTRACT:** We have investigated the interaction of the methylenide, CH( $X^2\Pi$ ,  $a^4\Sigma^-$ ) and methylene, CH<sub>2</sub>( $\tilde{X}^3B_1$ ,  $\tilde{a}^1A_1$ ) with H<sub>2</sub>O, employing the (P)MP $n$  ( $n = 2, 4$ ) techniques in conjunction with the sequence of correlation consistent basis sets aug-cc-pV $x$ Z,  $x = 2, 3$ , and 4. For the CH . . . OH<sub>2</sub> system, we have located four minima (m) and three transition states (ts) and for the CH<sub>2</sub> . . . OH<sub>2</sub>, five minima and four transition states. All our results have been corrected for zero-point energy (ZPE) and basis set superposition errors (BSSE), while for the most important m\_ structures, we report complete basis set (CBS) interaction limits. We also report fully optimized geometries, harmonic frequencies, dipole moments, Mulliken charges, and potential energy curves. The highest CH( $X^2\Pi$ ) . . . OH<sub>2</sub> ( $m1_2\Pi$ ) and CH<sub>2</sub>( $\tilde{a}^1A_1$ ) . . . OH<sub>2</sub> ( $m1_1A_1$ ) interactions are the result of electron transfer from the oxygen atom to the empty  $p_\pi$  orbitals of CH( $X^2\Pi$ ) and CH<sub>2</sub>( $\tilde{a}^1A_1$ ), respectively (ylide-like structures). At the (P)MP4/AQZ//MP2/ATZ level, including ZPE, BSSE, and CBS extrapolation, we obtain  $\Delta E_0(\text{BSSE})+\text{CBS} = -9.36$  kcal/mol at  $r_{C\dots O} = 1.752$  Å, and  $-9.73$  kcal/mol at  $r_{C\dots O} = 1.741$  Å for the  $m1_2\Pi$  and  $m1_1A_1$ , respectively. © 2005 Wiley Periodicals, Inc. *Int J Quantum Chem* 104: 497–511, 2005

## Introduction

**Y**lides are reactive intermediates that undergo synthetically useful transformations, defined as compounds in which a positively charged atom

from group 15 (VA) or 16 (VIA) of the periodic table is connected to a carbon atom carrying an unshared pair of electrons [1]. One method of synthesizing this class of compounds is by the interaction of carbenes with a nucleophile related to elements of group 15 or 16. For instance, in a well-known textbook of organic chemistry [2], the structure of prototypical nitrogen ylide is written as R<sub>3</sub>N<sup>+</sup>–CH<sub>2</sub><sup>–</sup>. During the past two decades, there has been a

*Correspondence to:* A. Mavridis; e-mail: mavridis@chem.uoa.gr  
Contract grant sponsor: Hellenic Scholarship Foundation (IKY).

growing interest in the use of carbonyl ylides for the synthesis of oxygenated heterocycles (see Ref. [1] and references therein).

Now, methyldiene, CH ( $X^2\Pi$ ) is one of the simplest and most reactive radicals, and it is believed to play an important role in atmospheric chemistry. Experimental work on the reaction of CH with small molecules such as N<sub>2</sub>, NO, N<sub>2</sub>O, CO, CO<sub>2</sub>, and H<sub>2</sub>O [3–5] and computational work on the reaction CH ( $X^2\Pi$  or  $a^4\Sigma^-$ ) + H<sub>2</sub>O [6–8] have been reported in the literature.

The parental carbene CH<sub>2</sub> ( $\tilde{X}^3B_1$ ), perhaps the most famous molecule in the evolution of computational quantum chemistry [9], is an important intermediate, also playing a significant role in planetary atmosphere. The reaction of CH<sub>2</sub> ( $\tilde{a}^1A_1$ ) with H<sub>2</sub>O producing CH<sub>3</sub>OH through an ylide-like intermediate, has been experimentally studied by mass spectrometric techniques [10]. Furthermore, the reactions CH<sub>2</sub> ( $\tilde{a}^1A_1$ ) + H<sub>2</sub>O → CH<sub>2</sub> ( $\tilde{X}^3B_1$ ) + H<sub>2</sub>O and CH<sub>2</sub> ( $\tilde{a}^1A_1$ ) + H<sub>2</sub>O → CH<sub>3</sub> + OH, the formation of methanol and of formaldehyde, have been investigated with laser-induced fluorescence detection under quasi-stationary and first order conditions [11, 12], while the first of the reactions above was also studied by laser flash photolysis/laser absorption methods [13].

The first computational work on the system CH<sub>2</sub>( $\tilde{a}^1A_1$ ) . . . OH<sub>2</sub> was done in 1980 by Harding et al. [14], where they calculated two minima, and in 1981 by Eades et al. [15], who calculated the three lowest configurations corresponding to two minima and one transition state. In the following years, the global minimum [16–20], the second minimum [21], the third minimum [19], and a transition structure [19] were studied. Previous theoretical work on the CH . . . OH<sub>2</sub>, CH<sub>2</sub> . . . OH<sub>2</sub> systems is summarized in Table I.

In the present report, we undertake a systematic study of the interaction of CH ( $X^2\Pi$ ,  $a^4\Sigma^-$ ), CH<sub>2</sub> ( $\tilde{X}^3B_1$ ,  $\tilde{a}^1A_1$ ) with H<sub>2</sub>O, using Møller–Plesset (MP) perturbation theory and relatively large basis sets. We report fully optimized geometries, interaction energies, harmonic frequencies, dipole moments and Mulliken charges, trying at the same time to understand the CH . . . OH<sub>2</sub>, and CH<sub>2</sub> . . . OH<sub>2</sub> interaction mechanisms.

## Methodological Details

The CH . . . OH<sub>2</sub>, CH<sub>2</sub> . . . OH<sub>2</sub> calculations were performed using, for all atoms, the augmented cor-

relation consistent series of basis sets, aug-cc-pVxZ (AxZ),  $x = 2(D), 3(T), 4(Q)$  of Dunning and coworkers [22]. The interaction between (CH, CH<sub>2</sub>) + H<sub>2</sub>O is such (vide infra) that there is no need for a multireference approach. Therefore, we have used the single reference MP perturbation theory, MP2 and MP4, for the singlets, and UMP2, UMP4, PMP2, and PMP4 for the doublets, triplets, and quartets, as implemented in the Gaussian 94 [23a] and Gaussian 98 [23b] suite of codes. All structures were fully optimized at the above correlated levels, with the exception of UMP4/ATZ and UMP2, UMP4/AVQZ, where single point calculations were performed at the (U)MP2/ATZ geometry. The “very tight” option of the program was used, while the energies were converged to  $\sim 0.01 \mu E_h$  with corresponding root mean square (rms) deviation of the energy gradient with respect to nuclear coordinates of  $11 \mu E_h/\text{bohr}$ . Harmonic frequencies were calculated for all structures at the (U)MP2/(ADZ, ATZ) level of theory. Spin contamination of the UMP calculations is not alarming: the  $\langle S^2 \rangle$  values range from 0.7596 to 0.7711 (instead of 0.75) for the doublets, 2.0156 to 2.0161 (instead of 2.0) for the triplets, and 3.7540 to 3.7544 (instead of 3.75) for the quartets.

Because of the importance of basis set superposition error (BSSE) [24] in weakly or van der Waals interacting systems [25], the interaction energies were BSSE corrected [26]. The interaction energy  $\Delta E$  of a XY van der Waals molecule and the corresponding BSSE corrected value  $\Delta(\text{BSSE})$  are defined as follows [27]:

$$\Delta E = E_{XY}^s(XY) - E_X^s(X) - E_Y^s(Y) \quad (1)$$

$$\begin{aligned} \Delta E(\text{BSSE}) = & E_{XY}^s(XY) - E_{XY}^s(X) - E_{XY}^s(Y) + E_X^s(X) \\ & - E_X^s(X) + E_{XY}^s(Y) - E_Y^s(Y), \quad (2) \end{aligned}$$

where  $E_G^s(M)$  refers to the total energy of molecule M at the geometry G computed with basis set  $s$ . Within the method employed, relation (1) needs no correction with respect to basis set size for “infinitely” large, i.e., complete basis sets (CBS). We also recall that the MP approach is size-extensive, a particularly useful property in the present study. CBS limits were obtained by applying the simple exponential formula  $P(x) = P(\infty) + Ae^{-Bx}$ , where  $P$  is a generic property;  $n$  reflects the quality of the basis set;  $x = 2, 3$ , and  $4$ ; and  $A, B$  are freely adjustable parameters [28]. Finally, all our calculations are valence-correlated, i.e., the  $\sim 1s$  carbon

and oxygen orbitals were always kept doubly occupied.

## CH, CH<sub>2</sub>, and H<sub>2</sub>O Molecules

Total energies, geometries, and harmonic frequencies of CH( $X^2\Pi$ ,  $a^4\Sigma^-$ ), CH<sub>2</sub>( $\tilde{X}^3B_1$ ,  $\tilde{a}^1A_1$ ), and H<sub>2</sub>O( $\tilde{X}^1A_1$ ) molecules are reported in Tables II and III. At the highest level of calculation, (U)MP4/AQZ, the geometries of all three molecules are in very good agreement with the experiment [29–31]. The energy gap  $a^4\Sigma^- \leftarrow X^2\Pi$  of CH is  $T_0 = 16.2$  (16.6) kcal/mol at the UMP4(PMP4)/AQZ level (where  $P$  stands for “projected”), in fair agreement with the experimental value of  $17.11 \pm 0.18$  kcal/mol [29c, 29d]. The same can be said for the energy separation  $\tilde{a}^1A_1 \leftarrow \tilde{X}^3B_1$  of CH<sub>2</sub>, where at the (U)MP4[(P)MP4]/AQZ level, we obtain  $T_0 = 10.3$  [11.0] kcal/mol, as compared with the experimental value,  $T_0 = 8.998 \pm 0.014$  kcal/mol [30f]. Here, zero-point energies (ZPE) have been calculated at the (U)MP2/AQZ level (Table III), admittedly not in very good agreement with experiment (or best ab initio values), but fair enough for the purposes of the present work.

Now, and for reasons that will be useful in the following sections, we give the valence–bond–

Lewis (vbL) diagrams of all species involved in this work [Schemes (1)–(5); see also Refs. [9] and [32]].

From these icons, it is clear that, in general, the interaction energies of CH( $X^2\Pi$ ) and CH<sub>2</sub>( $\tilde{a}^1A_1$ ) with H<sub>2</sub>O, should be much larger than the corresponding interactions of CH( $a^4\Sigma^-$ ) and CH<sub>2</sub>( $\tilde{X}^3B_1$ ) + H<sub>2</sub>O. “Bonding” in the first pair with water is plausible through an electron transferring mechanism to the available  $2p_x$  and  $2p_{x,y}$  orbitals of CH( $X^2\Pi$ ) and CH<sub>2</sub>( $\tilde{a}^1A_1$ ) respectively, but shut off in the CH( $a^4\Sigma^-$ ), CH<sub>2</sub>( $\tilde{X}^3B_1$ ) pair.

## Results and Discussion

### CH . . . H<sub>2</sub>O

We have calculated four structures of the CH( $X^2\Pi$ ) . . . OH<sub>2</sub> complex, as shown in Figure 1, two minima (m) and two transition states (ts), and three CH( $a^4\Sigma^-$ ) . . . OH<sub>2</sub> structures (two m and one ts). Table IV presents absolute energies, BSSE-corrected dissociation energies  $\Delta E(\text{BSSE})$ ,  $\Delta E_0(\text{BSSE}) = \Delta E(\text{BSSE}) + \text{ZPE corrections}$ ; CBS limits are also given for the  $m1\_2\Pi$ ,  $m2\_2\Pi$ , and  $m1\_4\Sigma^-$  species. Tables V and VI list ZPEs, harmonic frequencies ( $\omega_e$ ), Mulliken charges, and dipole moments ( $\mu$ ) respectively.

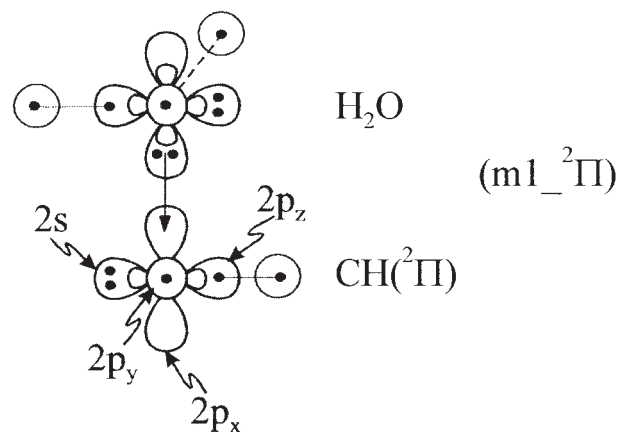

**FIGURE 1.** Geometries of the  $\text{CH}(^2\Pi) \dots \text{OH}_2$  and  $\text{CH}(^4\Sigma^-) \dots \text{OH}_2$  minima. Bond distances in Å at the UMP2/ATZ level.

At the PMP4/AQZ-CBS level, the interaction energy of  $\text{m1}_2\Pi$  (global minimum,  $C_1$ ) is  $\Delta E(\text{BSSE}) = -13.7$  kcal/mol, or  $\Delta E_0(\text{BSSE}) = -9.36$  kcal/mol, using the ATZ-ZPE corrections. The interaction takes place by charge transfer from the water oxygen atom to the empty  $2p_x$  orbital of the  $\text{CH}(^2\Pi)$  state, Scheme (1), forming an ylide-like complex at  $r_{\text{C}\dots\text{O}} = 1.752$  Å (Fig. 1). Corresponding literature results at the UMP2/6-31G\*\* [6] and UMP2/6-31G\* (d) [7] are  $\Delta E = -14.3$  kcal/mol,  $r_{\text{C}\dots\text{O}} = 1.868$  Å, and  $-15.3$  kcal/mol,  $r_{\text{C}\dots\text{O}} = 1.832$  Å, respectively.

However, no BSSE corrections have been applied in Ref. [6], while the results reported by Jursic [7] lack both ZPE and BSSE corrections. At the UMP4(SDQ)/CBSB4//UMP2/6-31G\* (d) level, Jursic gives  $\Delta E = -8.5$  kcal/mol. It is interesting that correcting the  $\Delta E$  value of Jursic [7] for ZPE and BSSE at the UMP4(SDTQ)/ADZ level (slightly better than that of Ref. [7]), using our results (Table IV), one obtains  $\Delta E = -8.5 + 4.1 + 2.1 = -2.3$

kcal/mol, showing the importance of ZPE and BSSE corrections for weakly interacting systems.

Increasing the symmetry of m1\_2 $\Pi$  from C<sub>1</sub> to C<sub>s</sub> the ts1\_2 $\Pi$  transition state (one imaginary frequency) is obtained, reflecting a pivotal movement of H<sub>2</sub>O around the C...O axis [Fig. 1(b)]. The  $\Delta E_0(\text{BSSE})/\text{PMP4-ATZ}$  "interaction" energy is -8.3 kcal/mol, larger by 0.30 kcal/mol than the m1\_2 $\Pi$

complex at the same level (Table IV). Obviously, the interaction mechanism of m1\_ and ts1\_2 $\Pi$  species are identical, but the latter's equilibrium distance  $r_{\text{C}\dots\text{O}} = 1.792 \text{ \AA}$ , is 0.04  $\text{\AA}$  larger than that of the former.

Figure 3 shows the potential energy curve (PEC) of the m1\_2 $\Pi$  HC...OH<sub>2</sub> interaction at the MP2/ATZ level, maintaining the equilibrium geometries

TABLE VI

Atomic Mulliken charges q and dipole moments  $\mu$ (Debye) of the  $\text{CH}(X^2\Pi) \dots \text{OH}_2$  and  $\text{CH}(a^4\Sigma^-) \dots \text{OH}_2$  complexes at the UMP2/ATZ level<sup>a</sup> (see Fig. 1).

$\mu$	3.955	3.321	3.318	3.763	2.852	2.541	1.836

<sup>a</sup> Mulliken charges and dipole moments of the free CH and H<sub>2</sub>O at the UMP2/ATZ level are as follows, CH(<sup>2</sup>Π):  $q_{\text{C}} = -0.42$ ,  $\mu = 1.515$  Debye; CH(<sup>4</sup>Σ<sup>-</sup>):  $q_{\text{C}} = -0.44$ ,  $\mu = 0.608$  Debye; H<sub>2</sub>O:  $q_{\text{O}} = -0.43$ ,  $\mu = 1.859$  Debye.

**FIGURE 2.** Geometries of the CH<sub>2</sub>( $\tilde{a}^1A_1$ ) ... OH<sub>2</sub> and CH<sub>2</sub>( $\tilde{X}^3B_1$ ) ... OH<sub>2</sub> minima. Bond distances in Å at the (U)MP2/ATZ level.

of the free CH( $X^2\Pi$ ), H<sub>2</sub>O fragments along the interaction coordinate.

In both cases  $m1_2\Pi$  and  $ts1_2\Pi$ , the bonding is succinctly represented by the vbL diagram shown in Scheme (6), indicating the charge transfer from an oxygen lone pair to the empty  $2p_x$ -orbital of the CH( $X^2\Pi$ ,  $B_1$  component). Indeed, from the Mulliken population analysis, 0.30 electrons are migrating to the  $2p_x$ -CH orbital. Note that the H<sub>1</sub>, C, O, and H<sub>3</sub> atoms in  $m1_2\Pi$  [Fig. 1(a)] are practically planar, the dihedral H<sub>1</sub>COH<sub>3</sub> angle being 0.85°. This mechanism suggests that a variety of Lewis bases, L, such as, NH<sub>3</sub> and CO, or even noble gases, can form systems of considerable stability with the  $X^2\Pi$  CH state.

Finally, the symmetric and asymmetric stretching modes of water in both  $m1_2\Pi$  and  $ts1_2\Pi$  structures are red shifted by 79–97 cm<sup>-1</sup>, as compared with the free H<sub>2</sub>O molecule, while the CH stretching is blue shifted by 20 and 43 cm<sup>-1</sup> in  $m1_2\Pi$  and  $ts1_2\Pi$ , respectively (Tables III and V).

The  $m2_2\Pi$  ( $C_s$ ) and  $ts2_2\Pi$  ( $C_{2v}$ ) structures constitute the second minimum and second transition state, respectively [Fig. 1(c) and (d)]. At the PMP4/AQZ, we calculate a van der Waals interaction energy for  $m2_2$ ,  $\Delta E = -3.78$  kcal/mol, reduced to  $\Delta E_0(\text{BSSE})[\text{CBS}] = -1.94[-1.97]$  kcal/mol, (Table IV) at  $r_{C\dots H} = 2.197$  Å, a significantly high interaction, considering its morphology and the atoms involved. The  $C_{2v}$   $ts2_2\Pi$  van der Waals

**FIGURE 3.** Potential energy curves at the UMP2/ATZ level of the  $m1_{-2}\Pi$   $\text{CH}(^2\Pi) \dots \text{OH}_2$  and  $m1_{-4}\Sigma^-$   $\text{CH}(^4\Sigma^-) \dots \text{OH}_2$  structures.

C—H...OH<sub>2</sub> PMP4/ATZ interaction is,  $\Delta E = -1.90$  kcal/mol reduced to  $\Delta E_0(\text{BSSE}) = -0.91$  kcal/mol, and estimated to about  $-1$  kcal/mol at the AQZ basis set, using our experience from the  $m2_{-2}\Pi$  interaction. It is interesting that at the AQZ basis set the  $ts2_{-2}\Pi$  structure was calculated to be a real minimum, but at the ATZ level, the previously calculated (ADZ) frequency of  $61 \text{ cm}^{-1}$  became  $20i \text{ cm}^{-1}$ . For both  $m2_{-2}\Pi$  and  $ts2_{-2}\Pi$  structures, the C—H bond length decreases by  $\sim 0.01 \text{ \AA}$  upon interaction with water as compared with the free  $X^2\Pi$  CH species (Table II). Jursic [7] reports  $\Delta E(\text{MP4SDQ}) = -3.4$  kcal/mol at  $r_{\text{C}\dots\text{H}} = 2.320 \text{ \AA}$  for the  $m2_{-2}\Pi$  structure; however, this value is reduced to  $-1.2$  kcal/mol if corrected by ZPE and BSSE using our results of the ADZ basis set (Table IV). In addition, concerning the  $ts2_{-2}\Pi$  structure, he concludes that it is a real minimum, although at the MP4SDQ level this configuration is unbound.

Turning now to the  $\text{CH}(^4\Sigma^-) \dots \text{OH}_2$  interaction, we report results for three structures, two minima  $m1_{-4}\Sigma^-$ ,  $m2_{-4}\Sigma^-$ , and one transition state,  $ts1_{-4}\Sigma^-$  [Fig. 1(e), (g) and (f)], all of  $C_s$  symmetry. No theoretical results have been reported before in the literature for these systems. The potential energy curve of the  $m1_{-4}\Sigma^-$  along the  $\text{CH} \dots \text{OH}_2$  interaction coordinate constructed as before at the MP2/ATZ level is depicted in Figure 3. Recalling that by singlet coupling two  $a^4\Sigma^-$  CH moieties the acetylene molecule is obtained, we expect the  $\text{CH} \dots \text{OH}_2$  interaction to be very similar to the corresponding  $\text{HCCH} \dots \text{OH}_2$  interaction [27]. In-

deed, from Ref. [27] at the MP4/AQZ//MP4/ATZ level, we have  $\Delta E_0(\text{BSSE})[\text{CBS}] = -1.88[-1.92]$  kcal/mol,  $r_{\text{HCCH}\dots\text{OH}_2} = 2.188 \text{ \AA}$ , and  $\varphi = 155.8^\circ$ , while for the  $m1_{-4}\Sigma^-$  at the MP4/AQZ//MP2/ATZ level we obtain  $\Delta E_0(\text{BSSE})[\text{CBS}] = -1.57[-1.69]$  kcal/mol,  $r_{\text{CH}\dots\text{OH}_2} = 2.151 \text{ \AA}$ , and  $\varphi = 146.2^\circ$  [Table IV, Fig. 1(e)]. The C—H bond length within the  $m1_{-4}\Sigma^-$  complex increases by  $0.01 \text{ \AA}$  as contrasted to the free  $a^4\Sigma^-$  CH, with a concomitant red shift of the C—H frequency of  $116 \text{ cm}^{-1}$ .

The interaction energies of  $m2_{-4}\Sigma^-$  and  $ts1_{-4}\Sigma^-$  structures [Fig. 1(g), (f)] at the MP4/AQZ level are  $\Delta E = -0.95$  and  $-1.03$  kcal/mol, respectively, but corrected for ZPE and BSSE these values become  $+0.2$  and  $-0.1$  kcal/mol, practically unbound.

### $\text{CH}_2 \dots \text{OH}_2$

We report six structures of the  $\text{CH}_2$  ( $\tilde{a}^1A_1$ )...OH<sub>2</sub> complex, three minima (m) and three transition states (ts), and three  $\text{CH}_2$  ( $\tilde{X}^3B_1$ )...OH<sub>2</sub> structures, two minima, and one transition state (Fig. 2). Table VII lists absolute energies, BSSE-corrected dissociation energies  $\Delta E(\text{BSSE})$ , and  $\Delta E_0(\text{BSSE})$ ; CBS limits are also listed for all five m-structures. Tables VIII and IX give ZPEs and harmonic frequencies, and Mulliken charges and dipole moments, respectively.

The  $m1_{-1}A_1$  (global minimum),  $m2_{-1}A_1$  (second minimum) just  $0.3$  kcal/mol above the  $m1_{-1}A_1$ , and  $ts1_{-1}A_1$  (first transition state) of point group symmetries  $C_s$ ,  $C_1$ , and  $C_s$ , respectively, are complexes of ylide character formed by charge transfer of about  $0.3 e^-$  from the oxygen to the empty  $2p_x$  orbital (perpendicular to the  $\text{CH}_2$  plane) of the  $\tilde{a}^1A_1$  state of methylene [see also Scheme (4)]. The vbL diagram shown in Scheme 7 clearly captures the physics of bonding.

The interaction energies  $\Delta E$  with respect to  $\text{CH}_2$  ( $\tilde{a}^1A_1$ ) + H<sub>2</sub>O at the MP4/AQZ//MP2/ATZ are  $-15.72$  and  $-15.45$  kcal/mol for the  $m1_{-1}A_1$  and  $m2_{-1}A_1$ , respectively. Correcting these values for ZPE and BSSE, we obtain  $\Delta E_0(\text{BSSE}) = -9.31$  and  $-8.99$  kcal/mol (Table VII). The final interaction energy of the global minimum  $m1_{-1}A_1$  at the CBS limit is  $-9.73$  kcal/mol. Assuming a similar CBS correction for the second minimum (m2), one estimates its interaction energy to be  $-9.4$  kcal/mol.

The corresponding values for the  $ts1_{-1}A_1$  structure at the MP4/ATZ//MP2/ATZ level are  $\Delta E = -10.52$  kcal/mol,  $\Delta E_0(\text{BSSE}) = -4.07$  kcal/mol, or

estimated to be about  $-5$  kcal/mol at the CBS limit, judging from our previous experience.

The  $\text{ts1}_1\text{A}_1$  structure is the transition state between two energetically equivalent  $\text{m2}_1\text{A}_1$  structures with respect to the pivotal movement of the  $\text{H}_2\text{O}$  molecule around the  $\text{C} \dots \text{O}$  axis of  $\text{m2}_1\text{A}_1$  [Fig. 2(b)], meaning that the energy barrier of this librational motion is  $4.0$  kcal/mol at the MP4/ATZ level. Figure 4 depicts the MP4/ATZ PEC of  $\text{CH}_2(\tilde{\text{a}}^1\text{A}_1) + \text{H}_2\text{O}$  along the  $\text{C} \dots \text{O}$  coordinate. Finally, in all three structures, the symmetric and asymmetric stretching of water is red shifted  $\sim 70\text{--}100$   $\text{cm}^{-1}$  and the methylene bending are red shifted by  $50\text{--}80$   $\text{cm}^{-1}$ .

The previous theoretical literature concerning the  $\text{m1}_1\text{A}_1$   $\text{CH}_2 \dots \text{OH}_2$  complex is significant [14–

20] (see Table I). Although, in general, all previous works give the  $\text{m1}_1\text{A}_1$  conformation as a minimum, the level of calculations are considerably lower than the present one and lacking systematic BSSE + ZPE corrections. This is reflected in a variety of conflicting results. For instance, the interaction energy of  $\text{C} \dots \text{O}$  ranges from  $-5.91$  [18] to  $-20.14$  [17] kcal/mol, or corrected for ZPE,  $-15.3$  [20] to  $-2.89$  [18] kcal/mol. Similarly,  $\text{C} \dots \text{O}$  distances range from  $1.758$  [20] to  $2.366$  Å. [18] The  $\text{m2}_1\text{A}_1$  structure was also examined in 1996 [21] at the MP2 and QCISD(T) + ZPE level, giving  $\Delta E_0 = -9.30$  (MP2) and  $-6.37$  [QCISD(T)] kcal/mol.

The rest of the  $\text{CH}_2(\tilde{\text{a}}^1\text{A}_1) \dots \text{OH}_2$  structures presently studied and shown in Figure 2 are a third minimum ( $\text{m3}_1\text{A}_1$ ) and two transition structures

<sup>a</sup> Mulliken charges and dipole moments of the free CH<sub>2</sub> and H<sub>2</sub>O at the (U)MP2/ATZ level are as follows: CH<sub>2</sub>( $\tilde{a}^1A_1$ ):  $q_C = -0.80$ ,  $\mu = 1.814$  Debye; CH<sub>2</sub>( $\tilde{X}^3B_1$ ):  $q_C = -0.91$ ,  $\mu = 0.594$  Debye; H<sub>2</sub>O:  $q_O = -0.43$ ,  $\mu = 1.859$  Debye.

(ts2\_ and ts3\_<sup>1</sup>A<sub>1</sub>), all belonging to the C<sub>s</sub> point group. The ts2\_<sup>1</sup>A<sub>1</sub> is the transition state between two (energetically) equivalent m3\_<sup>1</sup>A<sub>1</sub> structures with a very small energy barrier (<0.2 kcal/mol, including ZPE corrections). At the MP4/AQZ//MP2/ATZ level, the m3\_<sup>1</sup>A<sub>1</sub> C...H interaction energy amounts to  $\Delta E = -5.75$  kcal/mol or  $\Delta E_0(\text{BSSE})[\text{CBS}] = -3.31[-3.36]$  kcal/mol, and practically the same in the ts2\_<sup>1</sup>A<sub>1</sub>. It is interesting

SCHEME 7.

to observe that we are dealing with a remarkably strong ( $-3.4$  kcal/mol) C...H "hydrogen bond" in both m3\_ and ts2\_<sup>1</sup>A<sub>1</sub> structures, probably the result of the positive end of the water hydrogen [H<sub>3</sub> in Fig. 1(d)] facing the cylindrically symmetric 2s (or 2s<sub>p<sub>z</sub></sub> hybrid) of the CH<sub>2</sub>  $\tilde{a}^1A_1$  state [Scheme (8)].

FIGURE 4. Potential energy curves at the (U)MP2/ATZ level of the m1\_<sup>1</sup>A<sub>1</sub> CH<sub>2</sub>( $\tilde{a}^1A_1$ )...OH<sub>2</sub> and m1\_<sup>3</sup>B<sub>1</sub> CH<sub>2</sub>( $\tilde{X}^3B_1$ )...OH<sub>2</sub> structures.

SCHEME 8.

Finally, and in accordance with the previously discussed strong C...HOH interaction, a red shifted O—H stretching interaction of  $\sim 200\text{ cm}^{-1}$  is calculated for both  $m3_-$  and  $ts2_-^1a_1$  structures. The  $ts3_-^1A_1$  transition state [Fig. 1(f)] concerns a CH...O interaction with  $\Delta E[\Delta E_0(\text{BSSE})] = -1.61[-0.49]$  kcal/mol.

We discuss now the interaction of  $\text{H}_2\text{O}$  with the  $\tilde{X}^3B_1$  state of  $\text{CH}_2$ . Looking at the electronic distribution of the  $\tilde{X}^3B_1$  [Scheme (5)], we expect weak van der Waals interactions between these two species, and indeed this is the case. No calculations have been reported so far on the  $\tilde{X}^3B_1$  state of  $\text{CH}_2 + \text{H}_2\text{O}$ .

We present results for two minima ( $m1_-^3B_1$ ,  $m2_-^3B_1$ ) and one transition state ( $ts1_-^3B_1$ ), all of geometrical  $C_s$  symmetry [Fig. 2(g), (h), and (i)]. The H...O interaction energy of  $m1_-^3B_1$  is  $\Delta E = -1.78$  kcal/mol at the MP4/AQZ//MP2/ATZ, or including ZPE and BSSE corrections,  $\Delta E_0(\text{BSSE})[\text{CBS}] = -0.59[-0.66]$  kcal/mol (Table VII). Figure 4 shows the PMP2/ATZ potential curve of  $m1_-^3B_1$  along the H...O coordinate.

The  $ts1_-^3B_1$  is the transition state between two equivalent (mirror images) geometries of  $m1_-^3B_1$ , but the total energy differences between the  $m1_-^3B_1$  and  $ts1_-^3B_1$  is negligible, making the two structures practically indistinguishable. Contrasting the total energies of  $m1_-^1A_1$  and  $m1_-^3B_1$  corrected for ZPE, BSSE and including the CBS limit at MP4/AQZ level, it is seen (Tables II, III, and VII) that the global minimum of the  $\text{CH}_2\cdots\text{OH}_2$  complex is the  $m1_-^3B_1$  state by  $-1.97$  kcal/mol. However, considering our MP4/AQZ  $\tilde{a}^1A_1 \leftarrow \tilde{X}^3B_1$  energy splitting of 11.04 kcal/mol (Tables II and III), larger by 2.0 kcal/mol from the experimental value [26], we can claim with confidence that the  $m1_-^1A_1$  and  $m1_-^3B_1$  states are in essence degenerate. Lastly, in the  $m2_-^3B_1$ , at the MP4/AQZ//MP2/ATZ level, the H...C interaction energy is  $\Delta E = -1.71$  kcal/mol, reduced to  $-0.47$  kcal/mol by adding the ZPE and BSSE corrections, or  $-0.48$  kcal/mol at the CBS limit (Table VII).

## Synopsis

Employing the (P)MP $n$  ( $n = 2, 4$ ) technique in conjunction with the sequence of correlation consistent basis sets aug-cc-pV $x$ Z,  $x = 2, 3$ , and 4, we have systematically examined the weakly interacting systems  $\text{CH}(\tilde{X}^2\Pi, a^4\Sigma^-) + \text{H}_2\text{O}$  and  $\text{CH}_2(\tilde{X}^3B_1, \tilde{a}^1A_1) + \text{H}_2\text{O}$ . For the  $\text{CH}\cdots\text{OH}_2$  system, we have located four minima (m) and three transition states (ts, one imaginary frequency), and five minima and four transition states for the  $\text{CH}_2\cdots\text{OH}_2$ . All our results have been corrected for ZPE and BSSE, while for the most important  $m_-$  structures, we report complete basis set (CBS) interaction limits.

The highest  $\text{CH}(\tilde{X}^2\Pi)\cdots\text{OH}_2$  [ $m1_-^2\Pi$ , Fig. 1(a)] and  $\text{CH}_2(\tilde{a}^1A_1)\cdots\text{OH}_2$  [ $m1_-^1A_1$ ; Fig. 2(a)] interactions are the result of electron transfer from the oxygen atom to the empty  $p_\pi$  orbitals of  $\text{CH}(\tilde{X}^2\Pi)$  and  $\text{CH}_2(\tilde{a}^1A_1)$ , respectively. Specifically, and at the highest level of calculation (P)MP4/AQZ//MP2/ATZ, including ZPE, BSSE, and CBS extrapolation, we obtain  $\Delta E_0(\text{BSSE}) + \text{CBS} = -9.36$  kcal/mol at  $r_{C\cdots O} = 1.752$  Å, and  $-9.73$  kcal/mol at  $r_{C\cdots O} = 1.741$  Å for  $m1_-^2\Pi$  and  $m1_-^1A_1$ , respectively. The obvious similarity of the interaction mechanism causes practically the same "binding energies" and bond distances for both systems.

In the  $m1_-^4\Sigma^- \text{CH}\cdots\text{H}_2\text{O}$  complex [Fig. 1(e)], we obtain  $\Delta E_0(\text{BSSE}) + \text{CBS} = -1.69$  kcal/mol at  $r_{H\cdots O} = 2.151$  Å, close to the corresponding  $\text{HC}\equiv\text{CH}\cdots\text{OH}_2$  interaction [27], as expected.

Furthermore, in the  $\text{CH}_2\cdots\text{H}_2\text{O}$  complex, the  $m3_-^1A_1$  structure [Fig. 2(d)] has a remarkably strong C...H "hydrogen bond,"  $\Delta E_0(\text{BSSE}) + \text{CBS} = -3.36$  kcal/mol at  $r_{H\cdots C} = 2.098$  Å, while the  $m1_-^3B_1$  species [Fig. 2(g)] gives a  $\Delta E_0(\text{BSSE}) + \text{CBS} = -0.66$  kcal/mol at  $r_{H\cdots O} = 2.376$  Å.

Finally, the global minimum of the  $\text{CH}_2\cdots\text{OH}_2$  complex is the  $m1_-^3B_1$  state, lower than  $m1_-^1A_1$  by 1.97 kcal/mol. However, considering our MP4/AQZ  $\tilde{a}^1A_1 \leftarrow \tilde{X}^3B_1$  energy splitting of 11.04 kcal/mol, 2.0 kcal/mol larger than the experimental value [30f], we conclude that  $m1_-^1A_1$  and  $m1_-^3B_1$  states are in essence degenerate.

## ACKNOWLEDGMENT

D. T. expresses her gratitude to the Hellenic Scholarship Foundation (IKY) for financial assistance.
