Received: June 4, 2007

The electronic and geometric structures of gallium dinitride cation,  $\text{GaN}_2^+$  and gallium tetranitride cation,  $\text{GaN}_4^+$  were systematically studied by employing density functional theory (DFT-B3LYP) and perturbation theory (MP2, MP4) in conjunction with large basis sets, (aug-)cc-pVxZ,  $x = \text{T, Q}$ . A total of 7 structures for  $\text{GaN}_2^+$  and 24 for  $\text{GaN}_4^+$  were identified, corresponding to minima, transition states, and saddle points. We report geometries and dissociation energies for all the above structures as well as potential energy profiles, potential energy surfaces, and bonding mechanisms for some low-lying electronic states. The calculated dissociation energy ( $D_e$ ) of the ground state of  $\text{GaN}_2^+$ ,  $\tilde{X}^1\Sigma^+$ , is 5.6 kcal/mol with respect to  $\text{Ga}^+(^1\text{S}) + \text{N}_2(\text{X}^1\Sigma_g^+)$  and that of the excited state,  $\tilde{a}^3\Pi$ , is 24.8 kcal/mol with respect to  $\text{Ga}^+(^3\text{P}) + \text{N}_2(\text{X}^1\Sigma_g^+)$ . The ground state and the first excited minimum of  $\text{GaN}_4^+$  are of  $^1\text{A}_1(\text{C}_{2v})$  and  $^3\text{B}_1(\text{C}_{2v})$  symmetry with corresponding  $D_e$  of 11.0 and 43.7 kcal/mol with respect to  $\text{Ga}^+(^1\text{S}) + 2\text{N}_2(\text{X}^1\Sigma_g^+)$  for  $\text{X}^1\text{A}_1$  and  $\text{Ga}^+(^3\text{P}) + 2\text{N}_2(\text{X}^1\Sigma_g^+)$  for  $^3\text{B}_1$ .

## I. Introduction

Gallium nitrides are semiconducting materials with promising technological applications in microelectronics, nanomaterials, and optics. For example, they form single-crystal nanotubes that have great potential in nanoscale electronics, optoelectronics, and biochemical-sensing applications.<sup>1</sup> The use of GaN and InGaN in the active layer of high-efficiency light emitting diodes enables the emission of amber, green, blue, and ultraviolet light, which makes them ideal for displays and numerous other hi-tech applications.<sup>2</sup> Furthermore, with the use of gallium nitride structures, white light-emitting diodes can be obtained free of electrostatic fields, resulting in dramatic reduction of power consumption with beneficial economic and ecological consequences.<sup>3</sup> As a result, a number of experimental and theoretical studies of the electronic, structural and optical properties of the solid-phase material are reported in the literature.<sup>4</sup> Work on small clusters of GaN either experimental or theoretical is limited, even though information on the geometry and electronic structure of GaN clusters is essential for applications in microelectronics.

Several theoretical studies on  $\text{Ga}_x\text{N}_y$  species have been reported, for example on symmetric molecules,  $\text{Ga}_n\text{N}_n$  ( $n = 1-6^{5-8}$ ) as well as on the neutral  $\text{GaN}_2$  and  $\text{GaN}_4$  species.<sup>9-13</sup> In the case of the cations  $\text{GaN}_2^+$  and  $\text{GaN}_4^+$ , which are the subject of this paper, there are only two studies on  $\text{GaN}_2^+$ , one devoted to the ground electronic state,<sup>9</sup> the other to the ground and a very highly excited state.<sup>14</sup> As far as we know, there is nothing in the literature on the  $\text{GaN}_4^+$  cation.

In the present work the gallium dinitride cation,  $\text{GaN}_2^+$ , and gallium tetranitride cation,  $\text{GaN}_4^+$ , were systematically studied using both DFT (B3LYP/LANL2DZ) and MP (MP2, MP4/aug-cc-pVxZ,  $x = \text{T, Q}$ ) techniques. In total, 7 structures for  $\text{GaN}_2^+$  and 34 for  $\text{GaN}_4^+$  were determined corresponding to minima, transition states and saddle points. Total energies ( $E$ ), binding energies ( $D_e$ ) and geometries ( $r_e$ , angles) are reported for the 7

structures of  $\text{GaN}_2^+$  and for 24 of  $\text{GaN}_4^+$ , while the 10 highest transition states and saddle points calculated for  $\text{GaN}_4^+$  are provided as Supporting Information. Moreover, vibrational frequencies and potential energy profiles (PEP) and two-dimensional sections of potential energy surfaces (PES) of some low-energy structures of  $\text{GaN}_2^+$  and  $\text{GaN}_4^+$  are plotted. Finally, the bonding process is discussed.

In section II we describe the computational procedure followed, in section III we discuss the calculation on the triatomic  $\text{GaN}_2^+$  cation, in section IV we give our results on  $\text{GaN}_4^+$ , and, finally, in section V we present some conclusions and comments.

## II. Computational Procedure

For the  $\text{GaN}_2^+$  cation, the lowest lying singlet and triplet linear ( $\text{NNGa}^+$  and  $\text{NGaN}$ ) and bent structures were calculated, giving 7 distinct species. For the  $\text{GaN}_4^+$  cation, a preliminary sampling of the configuration space and bonding networks was performed using electronic structures of the combining fragments  $\text{N}_4 + \text{Ga}^+$ ,  $\text{N}_3 + \text{Ga}^+ + \text{N}$ ,  $\text{N}_2 + \text{GaN}_2^+$ ,  $\text{GaN}_3^+ + \text{N}$ , or  $\text{GaN}_2^+ + 2\text{N}$ . About 70 structures were checked for stability resulting in 34 singlet and triplet geometry optimized electronic structures of  $\text{GaN}_4^+$  at the B3LYP/LANL2DZ level of theory. B3LYP is a DFT functional using Becke's three-parameter gradient corrected functional<sup>15</sup> with the gradient corrected correlation of Lee, Yang, and Parr.<sup>16</sup> The Hay–Wadt LANL2DZ ECP<sup>17</sup> basis set consists of a pseudopotential for the core electrons (up to 3d electrons) of  $\text{Ga}^+$  and a double- $\zeta$  quality basis set, for the 2 outer electrons of  $\text{Ga}^+$ , ( $4s^24p^0$ ), and the 7 electrons of N, i.e., ( $3s3p$ )  $\rightarrow$  [ $2s2p$ ]<sub>Ga</sub> and ( $10s5p$ )  $\rightarrow$  [ $3s2p$ ]<sub>N</sub>.

Subsequently, all 7 structures of  $\text{GaN}_2^+$  and the 17 lowest structures of  $\text{GaN}_4^+$  were fully optimized at the MP2/aug-cc-pVTZ level of theory, using second-order perturbation theory and the augmented correlation-consistent basis of Dunning,<sup>18</sup> aug-cc-pVTZ (referred to as atz), i.e., ( $21s14p10d2f$ )  $\rightarrow$  [ $7s6p4d2f$ ]<sub>Ga</sub> and ( $11s6p3d2f$ )  $\rightarrow$  [ $5s4p3d2f$ ]<sub>N</sub>, thus involving

151 (GaN<sub>2</sub><sup>+</sup>) and 243 (GaN<sub>4</sub><sup>+</sup>) contracted Gaussian functions. For reasons of comparison additional MP2 calculations were performed using a different basis set, the 6-311+G(2df),<sup>19</sup> a split-valence triple-ζ basis set with diffuse and polarization functions for the ground state of GaN<sub>2</sub><sup>+</sup> and for three structures of GaN<sub>4</sub><sup>+</sup>. Furthermore, for the two lowest states of the GaN<sub>2</sub><sup>+</sup>, MP2 calculation were carried out using Dunning's basis sets<sup>18</sup> cc-pVTZ (referred to as tz), cc-pVQZ (qz), and aug-cc-pVQZ (aqz). The contracted aqz basis set is [8s7p5d3f2g]<sub>Ga</sub>/[6s5p4d3f2g]<sub>N</sub>, thus consisting of 253 contracted Gaussian

functions. The qz basis set was also used for calculations on the two lowest minima of GaN<sub>4</sub><sup>+</sup>. Moreover, single point calculations at the fourth-order perturbation theory (MP4SDTQ), MP4/atZ//MP2/atZ, were carried out for the ground states of both cations and CCSD(T)/atZ for the GaN<sub>2</sub><sup>+</sup>. In all MP calculations the valence space of GaN<sub>2</sub><sup>+</sup>[GaN<sub>4</sub><sup>+</sup>] consists of 22[32] e<sup>−</sup>, i.e., 3d<sup>10</sup>(4s4p)<sup>2</sup> and 2[4]×2s<sup>2</sup>2p<sup>3</sup> on Ga<sup>+</sup> and N atoms, respectively. In the case of the GaN<sub>2</sub><sup>+</sup> cation, CASSCF (complete active space SCF)/aug-cc-pVTZ calculations were performed by allotting the 13 “valence” electrons in 12 valence orbitals (one 4s + three

**Figure 1.** MP2 vdW bond lengths and the dissociation energies correlating to the  $\text{Ga}^+ + \text{N}_2$  ( $D_{e2}$ ) of the ground state  $\tilde{X}^1\Sigma^+$  of  $\text{GaN}_2^+$  with respect to basis set size  $x$ ,  $x = \text{T}$  (triple),  $\text{Q}$  (quadruple), and type (augmented or not). The dotted lines correspond to the geometry optimization for the BSSE-corrected energy (MP2<sub>BSSE</sub>).

4p on Ga, and one 2s + three 2p on N) for 14 electronic structures, to check the MP2 results. Normally, MP2 will only yield the lowest state of a given spin multiplicity within a given symmetry point group. By using CASSCF method, it is possible to determine other singlet or triplet states of different spatial symmetry (e.g.  $1^3\Sigma^+$ ,  $1^3\Pi$  or  $1^3\Delta$ ) that may lie between the lowest singlet ( $\tilde{X}^1\Sigma^+$ ) and triplet state ( $\tilde{a}^3\Pi$ ) of  $\text{GaN}_2^+$  calculated by MP2. In general, CASSCF is not sufficient for describing electron correlation effects; however, for the present purposes it is considered to be appropriate.

For all structures at all levels of theory the basis set superposition error (BSSE) was estimated through the counterpoise technique,<sup>20</sup> because BSSE corrections are important in van der Waals systems<sup>21</sup> such as most of the structures studied here. The BSSE was calculated for the fragments with respect to which the particular  $D_e$  is reported. For example the BSSE for  $D_e$  with respect to  $\text{Ga}^+ + \text{N}_2$  was calculated with respect to these two species and the BSSE for  $D_e$  with respect to  $\text{Ga}^+ + 2\text{N}$  was calculated with respect to these three species. For the four lowest electronic states of  $\text{GaN}_2^+$  the MP2 geometry was optimized for the BSSE-corrected energy, i.e., MP2<sub>BSSE</sub>.

Finally, there are no size nonextensivity problems in the plotting of the potential energy profiles of  $\text{GaN}_2^+$  and  $\text{GaN}_4^+$ , with the relevant error being less than 0.2 mh.

All MP calculations were performed using the Gaussian 03 program package,<sup>22</sup> and the CCSD(T) and CASSCF calculations were done using MOLPRO 2006.1.<sup>23</sup>

### III. $\text{GaN}_2^+$

We calculated seven structures, six minima ( $\tilde{X}^1\Sigma^+$ ,  $\tilde{a}^3\Pi$ ,  $1^3B_2$ ,  $1^3\Sigma_u^+$ ,  $1^3\Delta_u$  and  $1^1\Sigma_g^+$ ), and one transition state ( $1^1A_1$ ) of the  $\text{GaN}_2^+$  cation. Total energies ( $E$ ), geometries ( $r_e$ , angles) and dissociation energies with respect to the  $\text{Ga}^+(^1\text{S or }^3\text{P}) + 2\text{N}(^4\text{S})$  ( $D_{e1}$ ) and  $\text{Ga}^+(^1\text{S or }^3\text{P}) + \text{N}_2(^1\Sigma_g^+)$  ( $D_{e2}$ ), calculated with different methods, and/or basis sets, are presented in Table 1. Table 2 gives the corresponding harmonic vibrational frequencies and IR intensities at the MP2/atz level of theory. The variation of the Ga-N bond length and the dissociation energy of the ground state  $\tilde{X}^1\Sigma^+$  with respect to  $\text{Ga}^+ + \text{N}_2$  with basis set size and type is given pictorially in Figure 1. In Figure 2 the optimized potential energy profiles (PEPs) of four structures of  $\text{GaN}_2^+$  have been plotted along the stretching motion of  $\text{Ga}^+\cdots\text{N}_2$  correlating with the limits  $\text{Ga}^+(^1\text{S or }^3\text{P}) + \text{N}_2(^1\Sigma_g^+)$

**Figure 2.** Potential energy curves of the  $\text{GaN}_2^+$  cation at the MP2/aug-cc-pVTZ level of theory. The dotted lines correspond to the BSSE-corrected potential energy curves.

for the singlet or the triplet states, respectively. In addition, the corresponding BSSE-optimized PEPs have been also plotted (dotted lines in Figure 2). The optimized two-dimensional section of potential energy surface (PES) of the lowest singlet electronic state of  $\text{GaN}_2^+$  is plotted in Figure 3. The potential energy profile of the lowest triplet electronic state is depicted in Figure 4.

The ground state of  $\text{GaN}_2^+$  cation,  $\tilde{X}^1\Sigma^+$ , is a linear van der Waals (vdW) system, consisting of the ground state  $\text{N}_2(^1\Sigma_g^+)$ , which has a triple bond  $\sigma^2\pi^2\pi^2$ , interacting via a  $\sigma$  vdW bond with  $\text{Ga}^+(^1\text{S})$ , i.e.,  $\text{N}\equiv\text{N}\cdots\text{Ga}^+$ . Both natural and Mulliken population analyses show practically no charge transfer. Our best geometry at MP2<sub>BSSE</sub>/aqz level (MP2/aqz geometry, which is optimized for the BSSE-corrected energy) is  $r_{\text{Ga-N}} = 2.829$  and  $r_{\text{N-N}} = 1.111$  Å. Comparing the results obtained with different basis sets (see Table 1, Figure 1) we observe that augmentation of the basis set with diffuse functions (aug-) results in shorter vdW bond length compared with the same quality nonaugmented basis set. However, the vdW bond length is increased for both augmented and nonaugmented basis sets when the geometry is optimized for the BSSE-corrected energy, with the difference between  $r_{\text{Ga-N}}$  of the two kinds of basis sets greatly decreased. So, in quadruple basis sets and after optimizing the geometry for the BSSE-corrected energy, the  $r_{\text{Ga-N}}$  distances become very similar for the MP2/qz and MP2/aqz level, 2.835 and 2.829 Å, respectively, whereas the  $r_{\text{N-N}}$  value remains the same at all levels of theory (Table 1). The B3LYP method gives a shorter  $r_{\text{Ga-N}}$  by 0.2 Å compared to the MP2 values.

Comparing the  $D_{e2}$  values, which is the binding energy of  $\tilde{X}^1\Sigma^+$  with respect to  $\text{Ga}^+(^1\text{S}) + \text{N}_2(^1\Sigma_g^+)$ , obtained using different basis sets and methods (cf. Table 1), we observe that the B3LYP/LANL2DZ compared to the results of the MP and CC methods, overestimates  $D_{e2}$ , giving  $D_{e2}(\text{BSSE}) = 10.12$  (7.40) kcal/mol, where the number in parentheses indicates the BSSE-corrected value. In general, the  $D_{e2}$  value obtained by the MP method without BSSE correction is larger in an augmented basis set than in the corresponding nonaugmented one, but the BSSE correction greatly reduces this difference in both T and Q basis sets (see Figure 1). Practically, there are only small variations in  $D_e$  when the BSSE is taken into account in all basis sets. At the MP2<sub>BSSE</sub>/cc-pVQZ and MP2<sub>BSSE</sub>/aug-cc-pVQZ levels of theory (optimizing the geometry for the BSSE-corrected energy),  $D_{e2}$  is 5.6 kcal/mol. The MP4/atz//

**Figure 3.** Potential energy surface of  $\tilde{X}^1\Sigma^+$  as a function of the Ga–||| distance (||| is the middle of triple bond N<sub>2</sub>) and the  $\theta$  angle represented by contour lines equally spaced by 0.0005 hartree at the MP2/aug-cc-pVTZ level of theory. The contour lines were drawn on the basis of the data calculated at the coordinates represented by the filled circles. ( $1^1A_1$  is the transition state connecting two equivalent  $\tilde{X}^1\Sigma^+$  minima.)

MP2/atZ  $D_{e2}$  value is the same with the corresponding MP2/atZ, indicating that the higher order of perturbation does not contribute significantly. Moreover, the CCSD(T)/atZ  $D_{e2}$  value is very similar to the MP2 result, being only 0.2 kcal/mol smaller than the corresponding MP2/atZ ( $T_1$  diagnostic is rather small 0.0119).

A comparison of the optimized PEP (solid) and the BSSE-optimized PEP (open circles in Figure 2) of the  $\tilde{X}^1\Sigma^+$  state of GaN<sub>2</sub><sup>+</sup>, along the stretching motion of Ga<sup>+</sup>⋯N<sub>2</sub> correlating with the limits Ga<sup>+</sup>(<sup>1</sup>S) + N<sub>2</sub>( $X^1\Sigma_g^+$ ), shows that the effect of BSSE on the PEP is the increase of the equilibrium bond length  $r_{\text{Ga-N}}$  by 0.16 Å and the decrease of the well depth by 1.4 kcal/mol, whereas the shapes of the PEP and BSSE-PEP are similar.

Previous calculations on the ground state of GaN<sub>2</sub><sup>+</sup> have been reported in two studies, one employing DFT(GGA)/DNP+d<sup>9</sup> and the other employing the DFT(B3LYP), MP2, and CCD methods combined with the relativistic effective core potentials for the core electrons of Ga<sup>+</sup> and valence Gaussian basis sets for the 3d<sup>10</sup>4s<sup>2</sup>4p<sup>1</sup> of Ga and the N atom.<sup>14</sup> At the DFT/DNP+d

**Figure 4.** Optimized potential energy profile of the GaN<sub>2</sub><sup>+</sup>  $\tilde{a}^3\Pi-1^3B_2$  with respect to the  $\phi$  angle.

level the state is reported to be quasi linear ( $\phi = 178^\circ$ ) with  $r_{\text{GaN}} = 2.99$  Å and  $D_{e2} = 4.16$  kcal/mol.<sup>9</sup> In ref 14 their B3LYP method gives  $r_{\text{GaN}} = 2.730$  Å. Their corresponding MP2 and CCD values are 2.699 and 2.762 Å. These values are shorter than our best value of 2.829 Å for the Ga–N equilibrium bond length at the MP2<sub>BSSSE</sub>/aqz level of theory.

The lowest energy bent structure of GaN<sub>2</sub><sup>+</sup> has  $1^1A_1$  symmetry and it is also a vdW structure with a Ga<sup>+</sup>(<sup>1</sup>S) cation interacting with the triple bond of N<sub>2</sub>( $X^1\Sigma_g^+$ ) forming a T-shaped molecule. It is the transition state (one imaginary frequency, cf. Table 2) between two equivalent minima at the ground state,  $\tilde{X}^1\Sigma^+$ , i.e.,

with a barrier of 4.3 kcal/mol. Note that the B3LYP/LANL2DZ method overestimates significantly the barrier to 10.0 kcal/mol, about twice the MP2 value. The optimized two-dimensional potential energy surface between the two  $\tilde{X}^1\Sigma^+$  minima and their transition state  $1^1A_1$  is plotted in Figure 3, at the MP2/atZ level, where the contours are discontinued in the region of the PES where there are no calculated points. As seen in Table 1 the dissociation energy of  $1^1A_1$  ( $D_{e2}$ ) with respect to Ga<sup>+</sup> + N<sub>2</sub> is only 1.84(0.95) kcal/mol, the distance between Ga<sup>+</sup> and the middle of the N≡N triple bond is rather large 3.285(3.411) Å and the angle  $\phi_{\text{NGaN}}$  is 19.3(18.6)<sup>o</sup> at the MP2(MP2<sub>BSSSE</sub>)/atZ level of theory. Again, the calculations show that there is practically no charge transfer from N≡N to Ga<sup>+</sup>.

The first excited state of GaN<sub>2</sub><sup>+</sup> calculated here is a linear triplet state  $\tilde{a}^3\Pi$  correlating with 2 N(<sup>4</sup>S) + Ga<sup>+</sup>(<sup>3</sup>P, first excited state). The N atoms form a  $X^1\Sigma_g^+$  with a triple bond  $\sigma^2\pi^2\pi^2$  and Ga<sup>+</sup> is connected to N<sub>2</sub> with a  $\sigma^1$  (which is formed between the empty 4p<sub>z</sub> orbital of Ga and the 2s<sup>2</sup> orbital of the adjacent N, where the first one gains about 0.1 e<sup>-</sup>) and a  $\pi^1$  (which is formed between the 4p<sub>y</sub><sup>1</sup> orbital of the Ga<sup>+</sup> and the  $\pi_y^2$  orbital) of N<sub>2</sub>, i.e.,  $\overline{\text{Ga}^+\cdots\text{N}\equiv\text{N}}$ . The natural population analysis for this

structure gives  $\text{Ga}^+$ :  $4s^{1.00}4p_z^{0.11}4p_x^0 4p_y^{0.92}$  indicating a small charge transfer from  $p_y(\text{Ga}^+)$  to  $\pi_y(\text{N}_2)$  and a back-donation from  $\sigma(\text{N}_2)$  to  $p_z(\text{Ga}^+)$ . The middle N atom gains about  $0.3 e^-$  and the other N loses  $\sim 0.3 e^-$ .

The reaction energy of  $\text{GaN}_2^+(\tilde{a}^3\Pi) \rightarrow \text{Ga}^+(^3\text{P}) + \text{N}_2(\text{X}^1\Sigma_g^+)$  is  $D_{e2} = 24.8$  kcal/mol, at the MP2<sub>BSSSE/aqz</sub> level of theory, (cf. Table 1, Figure 2), and the bond distances are  $r_{\text{Ga-N}} = 2.067$  and  $r_{\text{N-N}} = 1.096$  Å. The spin contamination of the UMP2 calculation is very small with  $\langle S^2 \rangle = 2.01$  instead of 2. The  $\tilde{a}^3\Pi$  minimum can also be considered as made of  $\text{GaN}^+(^4\Pi, \text{sixth excited state of GaN}^+)$  +  $\text{N}(^4\text{S})$ . The  $\text{N}_2$  of this structure has shorter  $r_{\text{N-N}}$  by about  $0.01$  Å than the free  $\text{N}_2$  molecule. As shown in Figure 2 the shapes of the PEP and BSSE-PEP of the  $\tilde{a}^3\Pi$  state are very similar, the latter curve having a longer  $r_e$  bond length by  $0.03$  Å and a less deep well by  $0.9$  kcal/mol at the MP2/atz level.

The triangular  $1^3\text{B}_2$  structure contrary to  $1^1\text{A}_1$  is a minimum and  $\text{Ga}^+(^3\text{P})$  interacts with the triple  $\text{N}\equiv\text{N}$  bond of  $\text{N}_2$ , with a binding energy of  $16.0$  kcal/mol at the MP2<sub>BSSSE/atz</sub> level; cf. Table 1. The distance between  $\text{Ga}^+$  and the middle of the triple bond ( $r_{\text{Ga-III}}$ ) and the angle  $\varphi_{\text{NGaN}}$  are  $2.036$  Å and  $31.6^\circ$ , respectively. The  $1^3\text{B}_2$  structure belongs to the surface of the  $\tilde{a}^3\Pi$  state and lies at  $7.4$  kcal/mol above  $\tilde{a}^3\Pi$  with a barrier of  $9$  kcal/mol along the path to the linear structure. The MP2/atz potential energy profile of the lowest triplet electronic state of  $\text{GaN}_2^+$  is depicted in Figure 4.

The frequency of the  $\text{N}\equiv\text{N}$  stretching mode is  $2186.2$   $\text{cm}^{-1}$  in the free  $\text{N}_2$  molecule at MP2/atz level. In the  $\tilde{\text{X}}^1\Sigma^+$  and  $\tilde{\text{A}}^1\text{A}_1$  structures the corresponding frequencies are red-shifted only by  $5$  and  $11$   $\text{cm}^{-1}$  as a result of the formation of the vdW bond (see Table 2). On the contrary the  $\tilde{a}^3\Pi$  and  $1^3\text{B}_2$  structures exhibit a large blue shift of  $1338$  and  $308$   $\text{cm}^{-1}$ , respectively, because the  $\text{Ga}^+-\text{N}$  bond is short and not a vdW bond, so the  $\text{N}_2$  is more rigid and cannot stretch freely. That is why, in the case of the linear  $\tilde{a}^3\Pi$ , the frequency of the stretching mode is increased considerably.

The last two minima,  $^3\Sigma_u^+$  and  $^3\Delta_u$ , listed in Table 1, correspond to linear symmetric structures,  $\text{N-Ga-N}^+$ , with bond distances  $r_{\text{Ga-N}} = 1.870$  and  $1.815$  Å, respectively. Two of the three atoms are excited, i.e.,  $\text{Ga}^+(^3\text{P}) + \text{N}(^4\text{S}) + \text{N}(^2\text{D})$ , and BSSE-corrected binding energies, with respect to them are  $170.1$  and  $128.8$  kcal/mol, respectively. Finally, the lowest lying linear symmetric singlet  $\text{N-Ga-N}^+$  state,  $^1\Sigma_g^+$ , calculated at  $267$  kcal/mol above the ground state is bound at the B3LYP/LANL2DZ level but repulsive at the MP2/atz level and unbound with respect to the ground state atoms  $\text{Ga}^+(^1\text{S}) + 2\text{N}(^4\text{S})$ . In ref 14 this singlet  $\text{NGaN}^+ ^1\Sigma_g^+$  was also calculated along with the ground state.

Comparing our results on the  $\text{GaN}_2^+$  cation at the MP2/atz level with B3LYP/LANL2DZ, which is a DFT method with a small basis set, we observe a fair agreement on the geometry (the largest difference being less than 11%) and on the calculated  $D_e$  with respect to the three separated atoms limit. But in the case of  $D_{e2}$  with respect to the  $\text{Ga}^+ + \text{N}_2$  the difference between the two methods is large, as for example, for the case of  $1^1\text{A}_1$ , where the BSSE-corrected MP2 method finds this state bound with respect to  $\text{Ga}^+ + \text{N}_2$  products by  $1$  kcal/mol and the DFT<sub>BSSSE</sub> unbound by  $0.8$  kcal/mol, but given that the bond is weak, the difference is acceptable. A larger difference is found in the calculated  $D_{e2}$  for  $\tilde{a}^3\Pi$ , where the MP2<sub>BSSSE</sub> value is  $23.3$  and the DFT<sub>BSSSE</sub> value is  $41.6$  kcal/mol. Moreover, differences are found in the relative energy of some structures as, for example, between the  $\tilde{\text{X}}^1\Sigma^+$  and  $1^1\text{A}_1$  structures, resulting in a

value for the barrier height for the isomerization  $\tilde{\text{X}}^1\Sigma^+ \rightarrow 1^1\text{A}_1 \rightarrow \tilde{\text{X}}^1\Sigma^+$ , which is twice the MP2 value.

#### IV. $\text{GaN}_4^+$

In the present work we have calculated 34 structures, 12 minima, and 22 transition states or saddle points of the  $\text{GaN}_4^+$  cation. The 10 highest transition states and saddle points are given as Supporting Information. The geometries of the remaining 24 structures at different levels of treatment are summarized in Figure 5. For convenience the structures have been labeled by three symbols, the first indicating the spin multiplicity (1 or 3), the second the kind of structure, i.e., whether it is a minimum (m) or a saddle point (s), and the third the energy rank of the structure; for instance,  $1s2$  means 1 = singlet, s = (saddle point), and 2 = second lowest energy structure. In Table 3 total energies ( $E$ ), dissociation energies  $D_{e1}$  with respect to  $\text{Ga}^+(^1\text{S})$  or  $^3\text{P}) + 4\text{N}(^4\text{S})$ ,  $D_{e1}$  with respect to  $\text{Ga}^+(^1\text{S})/\text{Ga}^+(^3\text{P}) + 2\text{N}_2(\text{X}^1\Sigma_g^+)$ , and  $D_{e3}$  with respect to  $\text{GaN}_2^+ + \text{N}_2(\text{X}^1\Sigma_g^+)$  or  $\text{Ga}^+ + \text{N}_4$  as appropriate in each case (see discussion below) are presented. Table 4 gives vibrational frequencies and IR intensities calculated for the six lowest lying singlet and eight lowest lying triplet structures of  $\text{GaN}_4^+$ . Figures 6–10 depict the optimized potential energy profiles with respect to  $\text{Ga}^+ + 2\text{N}_2$  or  $\text{GaN}_2^+ + \text{N}_2$  and the optimized two-dimensional potential energy surfaces between the two lowest minima ( $1m1$  and  $3m3$ ) and their two transition states ( $1s2$  and  $3s4$ ).

The ground state of  $\text{GaN}_4^+$ ,  $\tilde{\text{X}}^1\text{A}_1$ , is a triangular structure (Figure 5a,  $1m1$ ), which may be considered as either having two  $\text{N}_2(\text{X}^1\Sigma_g^+)$  interacting with  $\text{Ga}^+(^1\text{S})$  via two van der Waals (vdW) bonds or consisting of a  $\text{GaN}_2^+(\tilde{\text{X}}^1\Sigma^+)$  and a  $\text{N}_2(\text{X}^1\Sigma_g^+)$  interacting via a vdW bond forming an angle  $\varphi_{\text{NGaN}} = 71.8^\circ$ . Surprisingly, the angle  $\varphi_{\text{NGaN}}$  is less than  $90^\circ$  which would have been expected, since the two vdW  $\sigma$  bonds interact with two empty perpendicular p orbitals of  $\text{Ga}^+(^1\text{S})$ . The bond lengths  $r_{\text{N-N}}$  and  $r_{\text{Ga-N}}$  are practically the same as in  $\text{GaN}_2^+(\tilde{\text{X}}^1\Sigma^+)$  at all levels of theory (cf. Tables 1 and Figure 5). So, we expect that the MP2-optimized geometry for BSSE using the qz or aqz basis will be  $r_{\text{N-N}} = 1.11$  and  $r_{\text{Ga-N}} = 2.83$  Å, as in the case of  $\text{GaN}_2^+(\tilde{\text{X}}^1\Sigma^+)$ . The  $\text{N}\equiv\text{N}\cdots\text{Ga}$  segment is quasi linear in all basis sets and methods with the calculated value of the angle at  $174.7$ – $179.6^\circ$ . Natural population analysis (npa) shows that the N atom at the end loses about  $0.18 e^-$  and the N closer to Ga gains about  $0.16 e^-$ , leaving the Ga atom with a net positive charge of  $0.98 e^-$ .

The calculated reaction energies for  $\text{GaN}_4^+ \rightarrow \text{Ga}^+(^1\text{S}) + 2\text{N}_2(\text{X}^1\Sigma_g^+)$  and  $\text{GaN}_4^+ \rightarrow \text{GaN}_2^+(\tilde{\text{X}}^1\Sigma^+) + \text{N}_2(\text{X}^1\Sigma_g^+)$  are  $10.8$  and  $5.3$  kcal/mol at the MP2-BSSSE-corrected/qz level of theory (Table 3). The first one is twice as large as the second one; it is worth noting that the latter is similar to  $D_{e2}$  of  $\text{GaN}_2^+(\tilde{\text{X}}^1\Sigma^+)$  that involves the removal of only one  $\text{N}_2$  moiety at the same level of theory. In the case of  $\text{GaN}_2^+$  the geometry was optimized for the BSSE energy, so judging from the similarity of the two systems, we can estimate that the BSSE-optimized energy of the  $\text{GaN}_4^+$  for the above reactions will be  $11.0$  and  $5.4$  kcal/mol at the MP2<sub>BSSSE/qz</sub> or aqz level. The higher order of perturbation does not contribute significantly to the  $D_e$  of the above reactions; a single point calculation at the MP4/atz//MP2/atz level of theory gives  $D_e$  about  $0.1$  kcal/mol lower, and because the MP4 was not optimized we expect that the optimized MP4 values will be almost the same or a little bit larger than those of MP2. Finally, the B3LYP/LANL2DZ method gives reaction energies overestimated compared to MP2 values but in tolerable agreement (see Table 3).

Isomerization between two equivalent  $\tilde{\text{X}}^1\text{A}_1$  minima, as the wedge changes direction, occurs via a transition state, the linear

**Figure 5.** Optimized geometries of 24 structures of singlet and triplet GaN<sub>4</sub><sup>+</sup> species at (B3LYP/LANL2DZ) ⟨MP2/6-311G+(2df)⟩ {MP2/pVTZ} MP2/aug-cc-pVTZ [MP2/ cc-pVQZ] levels of theory, gray spheres ≡ Ga, black spheres ≡ N.

1s2 (Figure 5b), which has an increased  $r_{\text{Ga-N}}$  bond by  $\sim 0.2$  Å at the MP2/atz level of theory whereas the barrier to isomerization is 2.16 kcal/mol; see Table 3. Using the nonaugmented

basis set cc-pVTZ, or the 6-311+G(2df) set, the calculated barrier is reduced substantially to 1.20 and 0.83 kcal/mol, respectively. The DFT value is 1.42 kcal/mol. The optimized

and bending modes is different in the two basis sets. Compared to the frequencies of the modes of GaN<sub>2</sub><sup>+</sup>( $\tilde{X}^1\Sigma^+$ ) and N<sub>2</sub>, they show small shifts ranging from -33 to +34 cm<sup>-1</sup>. The two imaginary frequencies of 1s2 correspond to the bending of the linear N-N-Ga<sup>+</sup>-N-N in two dimensions.

**Figure 6.** Potential energy curves of the 1m1( $^1A_1$ ) and 1s2( $^1\Sigma_g^+$ ) states of the GaN<sub>4</sub><sup>+</sup> cation with respect to the  $r_{\text{Ga-N}}$  distance, at the MP2/aug-cc-pVTZ level of theory. Inset: Optimized potential energy profile of 1m1( $^1A_1$ )-1s2( $^1\Sigma_g^+$ ) with respect to the angle  $\varphi$ .

The second minimum calculated for GaN<sub>4</sub><sup>+</sup> is the 3m3( $^3B_1$ ) structure (Figure 5c) which is a bent structure similar to 1m1, but here the Ga<sup>+</sup> cation is in its first excited state  $^3P$ , so its components are Ga<sup>+</sup>( $^3P$ ) + 2N<sub>2</sub>( $X^1\Sigma_g^+$ ) or GaN<sub>2</sub><sup>+</sup>( $\tilde{a}^3\Pi$ ) + N<sub>2</sub>( $X^1\Sigma_g^+$ ). In this case, the angle  $\varphi_{\text{NGaN}}$  is 92.1°, about 20° larger than that of 1m1. The two N<sub>2</sub> are perpendicular to each other because they bind to two empty perpendicular p orbitals of Ga<sup>+</sup>. The reaction energies are 43.5 and 18.5 kcal/mol, respectively, for the two dissociation process given above at the MP2-BSE corrected/qz level of theory (Table 3), and we can estimate that the BSE-optimized energy will be 43.7 and 18.6 kcal/mol at the MP2<sub>BSE</sub>/qz or aqz level. These values are about 4 times higher than the corresponding values calculated for 1m1. The Ga<sup>+</sup>-N bonds of 3m3 are much shorter than those of 1m1, and they are not vdW bonds as in the case of 1m1. The spin contamination of UMP2 calculation is very small, with  $\langle S^2 \rangle = 2.02$  instead of 2.

The transition state between the two equivalent wedge 3m3 structures is the linear 3s4 species (Figure 5d). The energy barrier to inversion is 10.2 kcal/mol. Note that the DFT method overestimates this barrier by 6 kcal/mol (see Table 3). In Figure 8, the MP2/atz potential energy profiles of the 3m3( $^3B_1$ ) and 3s4( $^3\Pi_u$ ) states of the GaN<sub>4</sub><sup>+</sup> cation are plotted as the Ga<sup>+</sup> is being removed while the angle  $\varphi_{\text{NGaN}}$  is kept constant. In the inset, the optimized potential energy profile of 3m3( $^3B_1$ )-3s4( $^3\Pi_u$ ) with respect to the angle  $\varphi$  is drawn; a

**Figure 7.** Potential energy surface of  $1m1(^1A_1)-1s2(^1\Sigma_g^+)$  as a function of the Ga–N distance and the  $\varphi_{\text{NGa-N}}$  angle represented by contour lines equally spaced by 0.0002 hartree at the MP2/aug-cc-pVTZ level of theory. The contour lines were drawn on the basis of the data calculated at the coordinates represented by the filled circles.

**Figure 8.** Potential energy curves of the  $3m3(^3B_1)$  and  $3s4(^3\Pi_u)$  states of the  $\text{GaN}_2^+$  cation with respect to the  $r_{\text{Ga-N}}$  distance, at the MP2/aug-cc-pVTZ level of theory. Inset: Optimized potential energy profile of  $3m3(^3B_1)-3s4(^3\Pi_u)$  with respect to the angle  $\varphi$ .

contour plot of the potential energy surface showing the two  $3m3(^3B_1)$  minima and their transition state  $3s4(^3\Pi_u)$  is given in Figure 9.

Comparing the modes of  $3m3$  to those of  $\text{GaN}_2^+(\tilde{a}^3\Pi)$  and  $\text{N}_2$ , the  $\omega_2$  to  $\omega_7$  frequencies of  $3m3$  are shifted only by about  $\pm 20 \text{ cm}^{-1}$ . The corresponding  $\omega$  values of  $3s4$  are much more red-shifted, up to  $110 \text{ cm}^{-1}$ . The  $\omega_8$  ( $3m3$ , symmetric stretch of two  $\text{N}=\text{N}$ ) presents a large blue shift of  $1343 \text{ cm}^{-1}$  with respect to the free  $\text{N}_2$ , similar to the  $1338 \text{ cm}^{-1}$  shift in  $\text{GaN}_2^+(\tilde{a}^3\Pi)$ , whereas  $\omega_9$  ( $3m3$ ), which corresponds to asymmetric stretch, shows an even larger shift of  $1386 \text{ cm}^{-1}$ . The large blue shifts results from the fact that the  $\text{N}_2$  is more rigid and cannot stretch freely. In  $3s4$  the  $\omega_8$  and  $\omega_9$  are blue-shifted only by 192 and  $264 \text{ cm}^{-1}$ , which is consistent with the fact that the Ga–N bond is elongated compared to  $3m3$  and  $\text{N}_2$  has more freedom to stretch.

In  $3m3$  the natural population analysis shows that electrons are transferred to the  $\text{Ga}^+$  cation whose net charge is  $+0.88|e^-|$ , the N atoms at the end have a positive charge of about  $+0.28$  each, and the N atoms closer to Ga have gained  $0.22 e^-$ . A similar charge transfer exists in the  $3s4$  structure.

The  $3s5(^3B_2)$ ,  $3s6(^3B_2)$ , and  $1s8(^1A_1)$  structures (Figures 5e,f,h) lie at 20.5, 21.6, and 65.8 kcal/mol, respectively, above the lowest triplet structure,  $3m3$ . They are T-shaped and have very similar shapes consisting of either a triangular  $\text{GaN}_2^+$  and a  $\text{N}_2$  connected with a bond to  $\text{Ga}^+$ , or a linear  $\text{Ga}^+\text{NN}$  whose  $\text{Ga}^+$  interacts with the  $\text{N}_2$  triple bond. Although both triplet structures  $3s5$  and  $3s6$  may be thought of as consisting of  $\text{N}_2(X^1\Sigma_g^+) + \text{GaN}_2^+(^3\Pi)$  or  $\text{GaN}_2^+(^3B_2) + \text{N}_2(X^1\Sigma_g^+)$ , they differ in the actual values of the bond-lengths and, in fact, the  $\text{N}_2(X^1\Sigma_g^+) + \text{GaN}_2^+(^3\Pi)$  limit is more appropriate for  $3s5$  with a BSSE-corrected dissociation energy  $D_{e3}(\text{BSSE}) = 1.1 \text{ kcal/mol}$  and the  $\text{GaN}_2^+(^3B_2) + \text{N}_2(X^1\Sigma_g^+)$  limit for  $3s6$  with  $D_{e3}(\text{BSSE}) = 6.2 \text{ kcal/mol}$ . The optimized PEP of  $3s5$  and  $3s6$  structures are drawn as the  $\text{N}_2$  is removed in Figure 10. The npa shows that in  $3s5$   $\text{Ga}^+$  gains about  $0.1 e^-$ . The  $\text{GaN}_2^+$  species of the singlet  $1s8(^1A_1)$  is a highly excited state that has not been calculated here. The structure  $1s8$  has significantly smaller  $r_{\text{Ga-N}}$  distances than those of  $\tilde{X}^1\Sigma_g^+$  and  $\tilde{A}^1A_1$  of  $\text{GaN}_2^+$ , by more than  $1 \text{ \AA}$  (Table 1, Figure 5h). In this structure  $\text{Ga}^+$  is in the excited  $^3P$  state and the distance  $r_{\text{Ga-N}}$  does not indicate a vdW bond.

The  $1s7(^1A_g)$  and  $3s9(^3B_{1u})$  are both transition states of  $D_{2h}$  symmetry (Figure 5 and Table 4). Both states, singlet and triplet, contain  $\text{Ga}^+(^3P)$  and have  $r_{\text{Ga-N}} = 1.92 \text{ \AA}$ ,  $r_{\text{N-N}} = 1.13 \text{ \AA}$  and  $\varphi_{\text{NGa-N}} = 37^\circ$ , at the MP2/atZ level of theory.

The  $3m10(A'')$  and  $3m11(^3B_2)$  minima are an open and a cyclic structure, respectively (cf. Figure 5), having a triplet  $\text{N}_4$  species,  $^3A''$  and  $^3B_1$ , respectively, interacting with a singlet  $\text{Ga}^+(^1S)$ . The MP2 BSSE-corrected dissociation energy with respect to  $\text{N}_4 + \text{Ga}^+$  is 15.4 and 12.3 kcal/mol at MP2(BSSE)/atZ level of theory. The  $r_{\text{Ga-N}}$  bond is 2.32 and  $2.68 \text{ \AA}$ , respectively. In  $3m10$  the npa shows that there is a reallocation

**Figure 9.** Potential energy surface of  $3m3(^3B_1)-3s4(^3\Pi_u)$  as a function of the Ga–N distance and the  $\angle\text{NGaN}$  angle represented by contour lines equally spaced by 0.001 hartree at the MP2/aug-cc-pVTZ level of theory. The contour lines were drawn on the basis of the data calculated at the coordinates represented by the filled circles.

**Figure 10.** Potential energy curves of the  $3s5(^3B_2)$  and  $3s6(^3B_2)$  states of the  $\text{GaN}_4^+$  cation with respect to the  $r_{\text{Ga-N}}$  and the  $r_{\text{Ga=}}$  distance, respectively at the MP2/aug-cc-pVTZ level of theory.

of charge, i.e.,  $\text{Ga}^{+0.97}\text{N}_1^{+0.15}\text{N}_2^{-0.62}\text{N}_3^{+0.25}\text{N}_4^{+0.24}$  ( $\text{Ga}^+$  is bonded to  $\text{N}_2$ ).

The linear structures  $\text{N-N-N-Ga-N}^+$ ,  $3s12(^3\Sigma)$  and  $1m17(^1\Pi)$ , both have  $\text{Ga}^+(^3P)$  and the  $r_{\text{Ga-N}}$  bonds are  $\sim 1.86$  and  $1.70$  Å for the Ga–N bond at the end and for the bond in the middle in both structures. The  $3s12$  at the DFT level is predicted to be a minimum, but in MP2/atz it is a saddle point. In this study, for most of the electronic states calculated, the DFT method predicts the same minima as MP2/atz, but there are some exceptions, as for example the case of  $3s12$ .

The next electronic structures discussed, a singlet  $1s13(^1A_1)$  and a triplet  $3s16(^3B_1)$  (Figure 5m,p), contain the  $\text{N}_4$  moiety, which is formed from a triangular  $\text{N}_3$  and a single N atom, giving rise to a singlet  $\text{N}_4(^1A_1)$  and a triplet  $\text{N}_4(^3B_1)$  structure, respectively. A singlet  $\text{Ga}^+(^1S)$  is connected to N via a bond of 2.234 and 2.517 Å, respectively. The reaction energies of  $1s13 \rightarrow \text{N}_4(^1A_1) + \text{Ga}^+(^1S)$  and  $1s16 \rightarrow \text{N}_4(^3B_1) + \text{Ga}^+(^1S)$  are 21.3 and 4.7 kcal/mol, respectively.

The last structures examined at the MP2/atz level are the linear  $1s14(^1\Sigma)$  and  $3s15(^3\Sigma)$  having a linear  $\text{N}_4(^1\Sigma)$  and  $\text{N}_4(^3\Sigma) + \text{Ga}^+(^1S)$ , respectively. The  $r_{\text{Ga-N}}$  bond is 2.24 Å, and the binding energies are 19.2 and 17.8 kcal/mol, respectively. In the  $1s14$  electronic state the MP2/6-311G+(2df) calculation gives shorter bonds compared to the MP2/atz level; on the contrary, in the  $1m1$  and  $1s2$  by the former method the  $r_{\text{Ga-N}}$  was elongated (Figure 5).

The next seven electronic states shown in Figure 5 are calculated only with the DFT method. Judging from the first 17 electronic structures, where the geometries in B3LYP/LANL2DZ were in good agreement even with a small basis set with the MP2/atz level of theory, the next seven structures calculated only in DFT are expected to have similar geometries at the MP2/atz level, yet the energy ordering of these structures may change in an MP2 calculation, as can be seen in Table 3 for the first 17 structures were calculated in both MP2 and B3LYP methods.

## V. Synopsis and Remarks

Gallium nitrides are semiconducting materials with promising technological applications in microelectronics and optics, so the information on the geometry and electronic structure of small GaN clusters is essential for both basic knowledge and technological applications. In the present work employing density functional theory (B3LYP/LANL2DZ) and perturbation theory (MP2, MP4/aug-cc-pVxZ,  $x = T, Q$ ) the gallium dinitride cation,  $\text{GaN}_2^+$ , and the gallium tetranitride cation,  $\text{GaN}_4^+$ , were systematically examined for the first time. A total of 7 ( $\text{GaN}_2^+$ ) and 24 ( $\text{GaN}_4^+$ ) electronic structures were examined. Their geometries, dissociation energies, and harmonic frequencies are reported, and potential energy profiles, potential energy surfaces, and the bonding mechanisms of some lowest states are given. Our findings can be summarized as follows.

1. The ground state of  $\text{GaN}_2^+$  ( $\tilde{X}^1\Sigma^+$ ) is a linear van der Waals molecule  $\text{N}\equiv\text{N}\cdots\text{Ga}^+$  with  $r_{\text{Ga-N}} = 2.829$  Å and dissociation energy of 5.6 kcal/mol with respect to  $\text{Ga}^+(^1S) + \text{N}_2(\tilde{X}^1\Sigma_g^+)$

products. The Ga<sup>+</sup> cation has to overcome a barrier of 4.3 kcal/mol to shift from one N atom to the other one.

2. The next minimum is the  $\tilde{a}^3\Pi$  state (NNGa<sup>+</sup>,  $r_{\text{Ga-N}} = 2.067$  Å), and the reaction energy of GaN<sub>2</sub><sup>+</sup>( $\tilde{a}^3\Pi$ ) → Ga<sup>+</sup>(<sup>3</sup>P) + N<sub>2</sub>(X<sup>1</sup>Σ<sub>g</sub><sup>+</sup>) is 24.8 kcal/mol. On this potential energy surface, a local minimum <sup>1</sup>B<sub>2</sub> is found at 7.4 kcal/mol above the  $\tilde{a}^3\Pi$  state, and a barrier of 9 kcal/mol has to be overcome to shift to the  $\tilde{a}^3\Pi$  structure.

3. The ground electronic state of GaN<sub>4</sub><sup>+</sup> is a triangular structure of <sup>1</sup>A<sub>1</sub>(C<sub>2v</sub>) symmetry with a D<sub>e</sub> of 11.0 and 5.4 kcal/mol with respect to Ga<sup>+</sup>(<sup>1</sup>S) + 2N<sub>2</sub>(X<sup>1</sup>Σ<sub>g</sub><sup>+</sup>) and GaN<sub>4</sub><sup>+</sup> → GaN<sub>2</sub><sup>+</sup>( $\tilde{X}^1\Sigma^+$ ) + N<sub>2</sub>(X<sup>1</sup>Σ<sub>g</sub><sup>+</sup>), respectively. The energy of isomerization between two equivalent  $\tilde{X}^1A_1$  as the wedge changes direction via a linear state (N–N–Ga<sup>+</sup>–N–N), is 2.2 kcal/mol.

4. The first excited state of GaN<sub>4</sub><sup>+</sup> is also a triangular structure of <sup>3</sup>B<sub>1</sub>(C<sub>2v</sub>) symmetry with a D<sub>e</sub> = 43.7 and 18.6 kcal/mol with respect to Ga<sup>+</sup>(<sup>3</sup>P) + 2N<sub>2</sub>(X<sup>1</sup>Σ<sub>g</sub><sup>+</sup>) and GaN<sub>2</sub><sup>+</sup>( $\tilde{a}^3\Pi$ ) + N<sub>2</sub>(X<sup>1</sup>Σ<sub>g</sub><sup>+</sup>), respectively. The energy of isomerization of  $\tilde{a}^3B_1$  ← linear N–N–Ga<sup>+</sup>–N–N →  $\tilde{a}^3B_1$  is 10.2 kcal/mol.

5. The third (<sup>3</sup>A'') and the fourth (<sup>3</sup>B<sub>2</sub>) minima are an open and a cyclic structure, respectively, having a triplet N<sub>4</sub> structure. The dissociation energy with respect to N<sub>4</sub> + Ga<sup>+</sup> is 15.4 and 12.3 kcal/mol.

6. The B3LYP/LANL2DZ and MP2/aug-cc-pVTZ geometries were in fair agreement. But the energy ordering of some structures is not the same in the two methods, resulting in some DFT reactions energies to be significantly overestimated with respect to MP2 data for both GaN<sub>2</sub><sup>+</sup> and GaN<sub>4</sub><sup>+</sup>. Moreover, 2 structures out of 17, i.e., 3m11 and 3s12, which are a minimum and a saddle point at the MP2/atz level, respectively, are characterized as a saddle point and a minimum in the B3LYP method.

**Acknowledgment.** Financial support has been provided by the Greek General Secretariat for Research and Technology through a Greece–Slovakia bilateral collaboration program.

**Supporting Information Available:** The optimized geometries of 10 high lying structures of singlet and triplet GaN<sub>4</sub><sup>+</sup> species at B3LYP/LANL2DZ level of theory are provided. This material is available free of charge via the Internet at <http://pubs.acs.org>.
